Introduction

In our recent work, we have shown some remarkable differences in individual ICF channel cross-sections in ${}^{6,7}\text{Li}$ induced nuclear reactions [1]. It is observed that the cross-sections for deuteron-capture are of similar magnitude as the α -capture, in case of ${}^6\text{Li}$ projectile, while the triton-capture is dominant than α -capture in case of ${}^7\text{Li}$ projectile. Intuitively, we expect this behavior as triton while approaching the target sees lower Coulomb barrier compared to alpha particle approaching the target, hence the cross-section for t-capture is more compared to α -capture in case of ${}^7\text{Li}$ but this argument does not hold with limited ${}^6\text{Li}$ data with ${}^{209}\text{Bi}$ and ${}^{197}\text{Au}$ targets. For further investigation of this behavior in individual ICF data, we have performed experiment with ${}^{6,7}\text{Li}$ on ${}^{124}\text{Sn}$ target and utilized the available data for ${}^{6,7}\text{Li}$ on ${}^{159}\text{Tb}$ target.

Experimental details

The online and offline gamma ray measurements were carried out at 14UD BARC-TIFR Pelletron-Linac accelerator facility, Mumbai. The targets of ${}^{124}\text{Sn}$ were bombarded with ${}^{6,7}\text{Li}$ beams while ${}^{159}\text{Tb}$ was bombarded with ${}^6\text{Li}$ beam. In the online gamma measurement, a Compton suppressed clover detector placed at a distance of 25 cm from the target cen-

tre, at 125° , was used for the estimation of absolute cross section of populated reaction channels. In the offline gamma measurement, the targets with Al catcher (~ 1 mg/cm² thick) were placed normal to the beam direction so that the recoiling residues are stopped in target-catcher assembly and irradiated for 7-18 hrs. The irradiated target-catcher assembly was then stucked to the perspex sheet and the sheet was kept at a fixed distance (~ 10 cm) in front of the HPGe detector. The HPGe detector was surrounded by 2 mm thick Cu and Cd sheets and 5 cm thick Pb sheets to reduce the background. The energy calibration and absolute efficiency of both Clover and HPGe detector was carried out by using a set of calibrated radioactive ${}^{152}\text{Eu}$, ${}^{133}\text{Ba}$ and ${}^{241}\text{Am}$ sources placed at the same geometry as the target.

Results

The extracted cross-sections for α -capture and d-capture/t-capture for ${}^{6,7}\text{Li}+{}^{124}\text{Sn}$ are plotted in Figs. 1 (a-d). The available α -capture and t-capture data for ${}^7\text{Li}+{}^{159}\text{Tb}$ is taken from Ref. [2] and plotted in Figs. 2(a) and (c). The d-capture data was available for ${}^6\text{Li}+{}^{159}\text{Tb}$ in Ref. [3]. For α -capture, we have extracted the cross-sections from measured offline gamma data and plotted in 2 (b) and (d).

In Figs. 1 and 2, we have plotted the results for ${}^{6,7}\text{Li}+{}^{124}\text{Sn}$ and ${}^{6,7}\text{Li}+{}^{159}\text{Tb}$ reactions. As can be seen from the figures, (a) and (b) the α -capture is less than the t or d-capture at all the measured energies. In Figs. (c) and

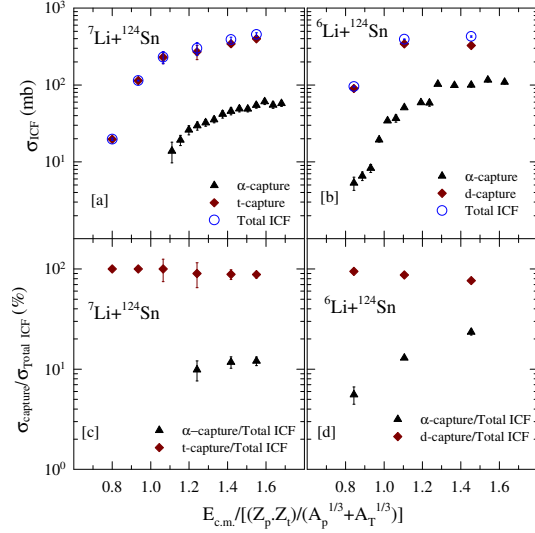

FIG. 1: (a) Comparison of α -capture and t-capture cross-sections in ${}^7\text{Li}+{}^{124}\text{Sn}$ reaction (b) Comparison of α -capture and d-capture cross-sections in ${}^6\text{Li}+{}^{124}\text{Sn}$ reaction. Individual percentage contributions of α -capture and t-capture in ${}^7\text{Li}$ and d-capture ${}^6\text{Li}$ is shown in (c) and (d) respectively.

(d), we have plotted the percentage contribution of α -capture and t-capture/d-capture. It is observed that for ${}^7\text{Li}$, t-capture is almost constant at all the energies and consumes 90 % of Total ICF while α -capture only contributes 10 %. For ${}^6\text{Li}$, d-capture contribution in Total ICF decreases with increasing energy while α -capture increases with energy. Also the d-capture contribution varies from 92-76 % in Total ICF from lowest to highest energy. This feature is not seen with heavy targets like ${}^{209}\text{Bi}$ and ${}^{197}\text{Au}$, where α -capture and d-capture have similar contribution in Total ICF [1]. More α -capture and d-capture data is required with ${}^6\text{Li}$ projectile for detailed understanding.

Summary and Conclusion

In summary, from the available experimental data, we have highlighted the differences in individual ICF cross-sections for ${}^6\text{Li}$ and ${}^7\text{Li}$ projectiles on ${}^{124}\text{Sn}$ and ${}^{159}\text{Tb}$ tar-

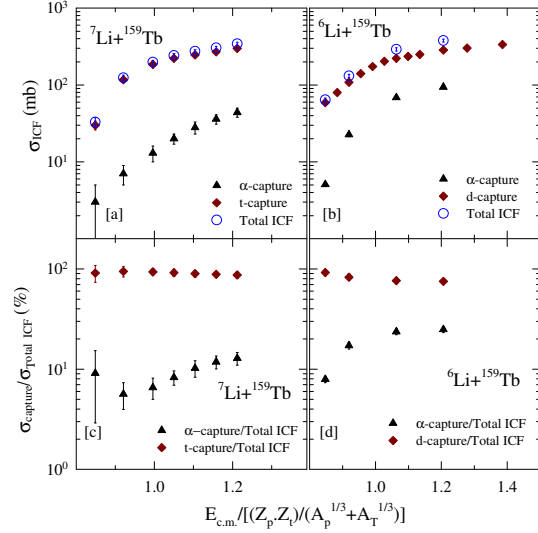

FIG. 2: Same as Fig. 1 but for ${}^{6,7}\text{Li}+{}^{159}\text{Tb}$ reaction.

gets. The individual ICF cross-sections imply that the d/t-capture cross-section is more than α -capture cross-section for both the targets contrary to observation made with ${}^{209}\text{Bi}$, ${}^{197}\text{Au}$ and ${}^{198}\text{Pt}$ [1]. It is also observed that the t-capture cross-section is consuming more than 90% of total ICF for ${}^7\text{Li}+{}^{124}\text{Sn}$ and ${}^7\text{Li}+{}^{159}\text{Tb}$ reactions at all the measured energies. In the case of ${}^6\text{Li}+{}^{124}\text{Sn}$ and ${}^6\text{Li}+{}^{159}\text{Tb}$ reactions, d-capture cross-section decreases from 92% to 76 % while α -capture cross-section increases from 8% to 24 % from below to above barrier energies. More data of d-ICF, α -ICF and t-ICF simultaneously for various systems is required for systematic understanding of ICF.
