### Introduction

PeV protons in the galactic center (GC) was detected by H.E.S.S. collaboration [1]. The highest possible energy of the proton from the Sgr A\* is proposed to be 170 PeV [2]. Proton having this much energy will interact with the molecular hydrogens present in plenty near the origin and background photons. The time scale of p-p interaction is very small compared to the p- $\gamma$  interaction time scale [3]. Also plenty molecular hydrogen presents in the Galaxy makes the p-p channel more efficient than other possible channels. p-p interactions will generate pions ( $\pi^0, \pi^+, \pi^-$ ). Neutral pions will decay into gamma rays, where as charged pions produces various neutrinos and anti neutrinos. In the mechanism  $p \rightarrow \pi^0 \rightarrow 2\gamma$  and  $p \rightarrow \pi^\pm \rightarrow 3\nu$ , the number ratio  $\gamma : \nu \sim 1 : 3$  and the corresponding energy ratio is  $\frac{E_\gamma}{E_\nu} \sim 2$  [4]. So maximum possible gamma energy and neutrino energy in this process will be  $[E_\gamma \sim \frac{1}{10}E_p]$  17 PeV and  $[E_\nu \sim \frac{1}{20}E_p]$  8.5 PeV respectively.

### $\pi$ production

High energy protons which are accelerated via LLCD mechanism[5], interacts with the cold ambient ISM, gives rise to  $\gamma$  and  $\nu$  through the decays of produced pions. We considered isotropic distribution of the accelerated proton  $dn(E_p)/dE_p$ , which gives rise to  $\pi^0$  emissivity given by [4],  $Q_{\pi^0}^{pp}(E_{\pi^0}) =$

$$cn_H \int_{E_p^{th}}^{E_p^{max}} \frac{dn(E_p)}{dE_p} \frac{d\sigma_{pp}(E_{\pi^0}, E_p)}{dE_{\pi^0}} dE_p \quad (1)$$

where  $n_H$  is the ambient hydrogen number density. The energy dependent pp crosssection expressed by [3]  $\sigma_{pp} = 34.3 + 1.88\ln(E_p/1TeV) + 0.25(\ln(E_p/1TeV))^2$  mb.

$E_p$ -independent approximations in scaling model with a parameterization of the differential cross section gives,[4]

$$\frac{d\sigma_{pp}(E_{\pi^0}, E_p)}{dE_{\pi^0}} \simeq \frac{\sigma_{pp}}{E_{\pi^0}} f_{\pi^0}(x) \quad (2)$$

where,  $x \equiv E_{\pi^0}/E_p$  and  $f_{\pi^0}(x)$  is expressed as [3, 4]

$$f_{\pi^0}(x) = 8.18x^{1/2} \left( \frac{1 - x^{1/2}}{1 + 1.33x^{1/2}(1 - x^{1/2})} \right)^4 \times \left( \frac{1}{1 - x^{1/2}} + \frac{1.33(1 - 2x^{1/2})}{1 + 1.33x^{1/2}(1 - x^{1/2})} \right) \quad (3)$$

Using all those parameterization  $\pi^0$  emissivity can be rewritten as,

$$Q_{\pi^0}^{pp}(E_{\pi^0}) = cn_H \sigma_{pp} \frac{dn(E_p)}{dE_p} \times Z_{p\pi^0}(\alpha) \quad (4)$$

here  $\alpha$  is the spectral index of the cosmic-ray spectrum and  $Z_{p\pi^0}(\alpha)$  is the spectrum-weighted moment of the inclusive cross section, also named as Z-factor and is given by[4],

$$Z_{p\pi^0}(\alpha) = \int_0^1 x^{\alpha-2} f_{\pi^0}(x) dx \quad (5)$$

### PeV neutrino and gamma ray flux

The emissivity for the production of gamma ray from pp interaction is expressed by the following [4] equation,

$$Q_\gamma^{pp}(E_\gamma) \simeq Z_{\pi^0\gamma}(\alpha) Q_{\pi^0}^{pp}(E_{\pi^0}) \quad (6)$$

\*Electronic address: rs\_sabyasachi@nbu.ac.in

here,  $Z_{\pi^0\gamma}(\alpha) = 2/\alpha$ , let us term this as  $Z_0$ .

The neutrino emissivity for different flavours takes these form [4],

$$Q_{\nu_\mu}^{pp}(E_{\nu_\mu}) \simeq 2[Z_{\pi^0\nu_\mu}(\alpha) + Z_{\mu\nu_\mu}(\alpha)]Q_{\pi^0}^{pp}(E_{\pi^0}) \quad (7)$$

$$Q_{\nu_e}^{pp}(E_{\nu_e}) \simeq 2Z_{\mu\nu_e}(\alpha)Q_{\pi^0}^{pp}(E_{\pi^0}) \quad (8)$$

factor 2 in the above equation implies that we are considering the sum of the neutrino and antineutrino emissivity. let us name  $Z_{\pi^0\nu_\mu}(\alpha)$  as  $Z_1$ ,  $Z_{\mu\nu_\mu}(\alpha)$  as  $Z_2$  and  $Z_{\mu\nu_e}(\alpha)$  as  $Z_3$ . These are the Z-factor corresponding to  $\nu_\mu$  production from pion decay, muon decay and  $\nu_e$  production from muon decay. They are evaluated following the equations[4] :

$$Z_1 = \frac{(1-r)^{\alpha-1}}{\alpha} \quad (9)$$

$$Z_2 = \frac{4[3-2r-r^\alpha(3-2r+\alpha-\alpha r)]}{\alpha^2(1-r)^2(\alpha+2)(\alpha+3)} \quad (10)$$

$$Z_3 = \frac{24[\alpha(1-r)-r(1-r^\alpha)]}{\alpha^2(1-r)^2(\alpha+1)(\alpha+2)(\alpha+3)} \quad (11)$$

where,  $r = (m_\mu/m_\pi)^2 = 0.467$

From eq. 4 the total neutrino emissivity for all flavours combined can be written as,

$$Q_\nu = cn_H Z \sigma_{pp} \frac{dn(E_p)}{dE_p} \times Z_{p\pi^0}(\alpha) \quad (12)$$

where,  $Z = 2[Z_1 + Z_2 + Z_3]$

Now,  $N_p = \frac{4\pi}{c} J_p$  is the steady state density  $= \frac{dn(E_p)}{dE_p}$  and  $R_{eff} \equiv \int dV/(4\pi r^2)$  is the effective radius, which is calculated to be between 1kpc to 10 kpc depending the shape of the halo considered around the galactic center[6]. The observed neutrino flux can be driven using[6],

$$J_\nu = J_\nu(E_\nu) = \frac{1}{4\pi} \int_0^1 dV \frac{Q_\nu}{4\pi r^2} = \frac{R_{eff}}{4\pi} \times Q_\nu \quad (13)$$

from equation 12 and 13 we derived the equation for the calculation of the neutrino flux,

$$J_\nu = n_H \sigma_{pp} Z R_{eff} J_p \times Z_{p\pi^0}(\alpha) \quad (14)$$

The gamma ray flux is expressed by,

$$J_\gamma = n_H \sigma_{pp} Z_0 R_{eff} J_p \times Z_{p\pi^0}(\alpha) \quad (15)$$

## Results

$n_H = 1cm^{-3}$ [3, 6] is considered. Although in various paper GC region ISM density is considered to be much higher  $n_H = 120cm^{-3}$  [7].  $J_p$  is calculated from cosmic ray spectra[8] comes  $\frac{2 \times 10^3}{E^{2.6}}$  in  $GeV^{-1}cm^{-2}s^{-1}sr^{-1}$

TABLE I: Flux calculation for different values of  $n_H$  and  $R_{eff}$  with spectral index value 3.

$n_H^a$	$R_{eff}^b$	$J_\nu^c$	$E_\nu^2 J_\nu^d$	$E_\gamma^2 J_\gamma^d$
1	1	$2.7 \times 10^{-28}$	$2 \times 10^{-14}$	$9.3 \times 10^{-14}$
120	1	$3.2 \times 10^{-26}$	$2.3 \times 10^{-12}$	$1.1 \times 10^{-11}$
1	10	$2.7 \times 10^{-27}$	$2 \times 10^{-13}$	$9.3 \times 10^{-13}$
120	10	$3.2 \times 10^{-25}$	$2.3 \times 10^{-11}$	$1.1 \times 10^{-10}$

<sup>a</sup>in  $cm^{-3}$

<sup>b</sup>in kpc

<sup>c</sup>in  $GeV^{-1}cm^{-2}s^{-1}sr^{-1}$

<sup>d</sup>in  $GeVcm^{-2}s^{-1}sr^{-1}$

## Conclusions

Higher flux value is observed for lower spectral index values. Sgr A\* can be a source of PeV neutrinos. Much higher sensitive detector may detect those neutrinos in near future.
